Highlights

• Located in a world-class producing petroleum province
• Shallow water depths (15–50 m)
• Moderate seismic and well coverage
• CO₂ storage plays in anticlines, fault sealed anticlines and saline aquifer stratigraphic traps
• Located proximal to CO₂ sources and infrastructure
• Special Notices apply, refer to Guidance Notes

The Assessment Areas straddle the shallow shelfal portion of Bass Strait where water depth range from 15 to 50 m. The areas are located in the western Central Deep part of the basin, adjacent to the onshore Seaspray Depression and overlap the western portion of the Southern Terrace (Figure 2). Geological control is provided by exploration wells and seismic surveys of varying quality that have tested top-Latrobe Group and intra-Latrobe Group petroleum targets. Indicative oil and gas discoveries at Barracouta, Dolphin, Golden Beach, Perch, Seahorse, Tarwhine, Mulloway and Whiptail, demonstrate the existence of top-Latrobe and numerous intra-Latrobe reservoir and seal pairs in the Area.
The basin developed during the Early Cretaceous as part of the break-up of Gondwana and extension between the Australian and Antarctic continents. Continued rifting into the Late Cretaceous generated a classic extensional geometry comprising a depocentre (the Central Deep) flanked by platforms and terraces. Early to mid-Eocene compression across much of the eastern portion of the southern margin saw reactivation of syn-rift faults and post-rift sediments, creating the present-day inversion structures. Several petroleum systems operate in the basin. The largest oil and gas fields are hosted by top-Latrobe Group (Eocene) shallow marine barrier sandstones with additional discoveries made in intra-Latrobe (Paleocene) coastal plain and deltaic channel sandstones.

The Release Areas offer a range of CO₂ storage play types including inversion-related anticlines, fault sealed anticlines and saline aquifer Saline aquifer stratigraphic traps, and migration dissolution/residual traps; stratigraphic traps are represented by pinch-outs and truncations across unconformities.

**Reservoir and seal elements**

**Gippsland Basin**

|---|---|
| Seals | **Reginal seals**

- Oligocene–Miocene marine carbonate Early Oligocene Wedge (EOW), Lakes Entrance formation (Seaspray Group)
- Eocene-Oligocene Gurnard Formation

**Intra-Latrobe Group seals**

- Paleocene marine Kate Shale (Halibut Subgroup)
- Campanian–Paleocene volcanics (several distinct horizons)

**Infrastructure**

The Assessment Areas are situated offshore in federal waters at the western extremity of pre-existing petroleum infrastructure in the Central Deep part of the Gippsland Basin. Onshore, brown coal-fired power stations in the Latrobe Valley include the Hazelwood, Loy Yang, Yallourn and Energy Brix power stations. These power stations constitute a large proportion of Victoria’s energy supply and are a major CO₂ emission source.

Offshore hydrocarbon production in the basin remains strong, and is being expanded by a new $4.4 billion investment to develop the Kipper Tuna Turrum project. The oil and gas resources are processed at the Longford gas processing facility and made available for the growing SE Australian energy market. The Longford facility is also a CO₂ emission source. Despite long term production, the Gippsland Basin is still recognised as a world class petroleum province, with crude oil of 3.34 Gt, condensate production of 1.5 Gt and gas production of 5.5 Gm³ in the 2010/2011 financial year.
